The New Dynamic Services

The information in this guidance is tailored to support new, existing and transitioning providers of the New Dynamic Services. This document complements the service’s contractual documents: the Service Terms, Procurement Rules and Balancing Services Glossary. In the event of any conflict or inconsistency between this document and the contractual documents, the latter shall prevail.

Dynamic Containment (DC), Dynamic Moderation (DM) and Dynamic Regulation (DR) make up our new suite of New Dynamic Services. Together they work to control system frequency and keep it within our licence obligations of 50Hz plus or minus 1%. DM provides fast acting pre-fault delivery for deviations between +/- 0.015 Hz and 0.2 Hz. DR is our staple slower pre-fault service. DC is our post-fault service.

Please note this does not include our Dynamic Firm Frequency Response (DFFR) service which is being replaced with these new dynamic services and phased out in FY23/24. Information on Dynamic FFR can be found on the ESO website.

DC is a fast-acting, post-fault service designed to arrest frequency in large-loss, low inertia scenarios. It delivers energy proportionally to the change in frequency, within +/-0.5 Hz of the target frequency value. It is particularly suited to act in the event of a sudden demand or generation loss. The DC low frequency (“DCL”) product went live in October 2020, followed by the launch of the DC high frequency service (“DCH”) in October 2021.

DM and DR are pre-fault services wherein providers make automatic adjustments in generation (or demand). DR provides a constant power response across the operational frequency range, reaching full delivery at a +/-0.2 Hz frequency deviation. DM responds between +/-0.1 Hz and +/-0.2 Hz, providing additional power to stabilise frequency as it moves closer to operational limits. DM and DR were launched in March 2022.

Following the Article 18 of the EBGL consultation which concluded on 28 October 2022. Our proposal to deliver a merged set of contractual documents for the three aforementioned services was approved by Ofgem. The documents include merged Service Terms, which describe the requirements for the provision of each of the services, and Procurement Rules, which describe the eligibility rules for participation in the services. Having received Ofgem’s approval on 10 February 2023 these terms will be live on the 1st of April 2023 and will include updates to allow Grid Supply Point (GSP) group aggregation for Dynamic Containment to align with DM and DR as well as changes to performance monitoring and grace periods as detailed in this document.

This guidance is published to support the onboarding of the new terms by our providers. It is designed to give additional information on the rules and recommendations regarding the delivery of these services, along with relevant use cases. This document will be updated outside of the response reform annual development cycle to allow for more frequent updates.
Service Criteria
Overview of the services

All three New Dynamic Services – **DC, DM and DR** – share the characteristics described below.

**A minimum response capacity** of 1 MW is required per response unit.

**A maximum response capacity** of 100 MW for DC and 50 MW for DM and DR is permitted per response unit.

**Automatic activation** is required from either generation or demand, or energy limited (e.g. battery) assets.

Energy limited assets have to comply with the **“state of energy” management rules**.

**Contract** delivery is done across four-hour EFA Blocks.

**Sell orders** may only be submitted in whole MWs.

We procure **low and high frequency services** separately.

Participation is open to **both Balancing Mechanism (BM) and non-BM** registered assets.

All services include the capability to **disarm and re-arm** in response to an instruction from NGESO.

**Aggregation** is possible when assets sit behind same GSP Group (subject to technical assurance being carried out on the risks associated with moving to GSP Group).

**Payments** are provided for availability only.

---

**Dynamic Containment (DC)**

This service is designed to help contain frequency within statutory limits +/- 0.5 Hz from the target frequency of 50 Hz.

**Dynamic Moderation (DM)**

This service is designed to help contain frequency within operational limits +/- 0.2 Hz from the target frequency of 50 Hz.

**Dynamic Regulation (DR)**

This service is designed to help contain frequency within operational limits +/- 0.2 Hz from the target frequency of 50 Hz.
In order to register as a provider for one or several of the New Dynamic Services, you are required to test your assets and submit proof of its capability to deliver, according to the following service specifications. Please refer to the next section of this guidance for more information on testing.

If you and your organisation are new to NGESO and to the SMP Portal, then it is required that you register directly via the portal using the following instructions.

The User should visit and bookmark the following link: https://portal.nationalgrideso.com/smp/s/login/

As a first time user you will need to click the "Register New Account" button. Users will be navigated to the first ‘screen’ to capture Registration.

**Registering New Primary User**

In order to access the SMP Portal, it is expected that upon initial registration the main or ‘primary’ contact (user) at your organisation/company will undertake the registration steps.

Registration involves submitting one’s contact details and their organisation/company details. The successive order is contact details followed by company details.

When entering email addresses or telephone numbers, standardised formats are expected, if a User/Contact does not submit field values compatible with the expected format then the field will be flagged in a red border with a prompt instruction. For example if an email address has been submitted with the incorrect format.

Once all of the fields have been completed on the User/Contact section, the “Next” button will no longer be shaded grey, instead it will be converted into a blue ‘button’, allowing you to proceed to the next step.

**Registering the Primary User’s Company**

The ‘Register new Account’ stage involves two pathways depending on the Company Status. If the User/Contact’s organisation is a UK Limited Company, they select the first checkbox. If the User/Contact’s organisation is a non-UK Company then they select the second checkbox.

Once the option is selected, the user clicks on the "Next" Button.

**Registering a UK Company**

The User/Contact will be prompted to search for the Company Name and the Company Registration Number.

- **For Company Name** - they will be expected to enter the name, which will trigger a lookup search/listing of similar names for the user to choose from.
- **For Company Registration Number** - they will be expected to enter the exact reference number, which will trigger a lookup search/listing for the user to select and confirm.

Please note that only valid and accurate Registration Numbers will be accepted and appear in the search exercise. If your Company is a UK Limited Company and the search listing is unsuccessful, you will need to reach out to your NGESO Account Manager by email.

Once a match has been found, the User/Contact must select the “Submit” button to proceed to the next step.

If the search result is incorrect or the User/Contact wishes to undertake a new search, then they are expected to click on the “Remove Company” link to refresh the search functionality.

For more information on this process, or for information on registering a non UK company click [here](#).

For technical support please contact: commercial.operation@nationalgrideso.com
The following section will give a step by step guide to submitting orders on EAC. If you and your organisation are new to NGESO and have yet to register to SMP, then it is required that you register there first, see page 10 for full instructions on how to do so. All participants must then be registered as a user for EAC, even after registering units on SMP.

After registering for EAC and logging in with 2-factor authentication the first step is to select that auction that you would like to bid into. All auctions with gates open can be found under the ‘Auctions’ tab.

After you have selected the auction that you would like to bid into you will need to select the unit you would like to use from the drop down menu.

Following this you will start to build and add your baskets (defined by EFA block). You will give your basket a name and a family name if these are looped baskets and add in the relevant information such as price volume and any child order or substitutable child orders as required.

Once all of the relevant information has been added the bid can be submitted.

After the auction results can be found in the results tab for your relevant unit, all results will be published on the Data Portal for all units.

Please note that bids can also be submitted via API, to obtain API credentials please contact the ESO.
Technical Guidance
Prior to participating in frequency services, all assets will need to have passed the pre-qualification testing described in the procurement guidelines and supporting documents.

Asset testing consists of 4 types of tests, Duration, Frequency Sweep, Step and Live system testing. These tests are designed to show that the asset can deliver the service in line with each individual service design specifications. These tests can be conducted on an individual assets level or as an aggregated unit.

Asset testing is to be signed off by a technical engineer appointed by the provider and the completed test report is then to be sent to us.

In addition to service testing the asset providing the service as part of onboarding, the provider will need to test for Operational Metering, Performance Monitoring through the Data Concentrator, Ancillary Service Dispatch Platform (ASDP) testing if it is a non-BM unit and any requirement needed if the Unit is registered as a BM unit. All information regarding these test can be found on the ESO website.

An example of a service design is provided below. Testing is needed to confirm that a particular asset can deliver under these requirements.

### Service description - DC

DC is a fast-acting frequency response service to contain frequency within the statutory range of +/-0.5Hz in the event of a sudden demand or generation loss. The service delivers very quickly and proportionally to frequency deviation.

Performance monitoring

This section provides information on the application of the performance monitoring methodology for the New Dynamic Services. Some examples are given for particular scenarios including Low only services, High only services and Low and High services. Reference of the PerfMon_Excel calculator sheet provided with this document is used throughout the section. In the event of any conflict or inconsistency between this document and the Service Terms, the latter shall prevail.

Lags and ramp limits

The lags and ramp limits for each of the dynamic services are defined in Table 4.

Table 4: Lags and ramp limits.

<table>

Service Terms

Recalling the main definitions for Performance Monitoring from the Service Terms:

Availability Payments

From the Service terms, the payment formula is:

$$S_{ie} = \left( \sum_j^{CEB} \text{Round} \left( P_{ij} \times V_{ij} \times 0.5 \right) \times F_{ij} \right) \times K_e$$

Where

- $S_{ie}$ is the settlement value for the relevant Product calculated in respect of Response Unit $i$ for the applicable Contracted EFA Block $e$
- $\Sigma_j$ is the summation over the Settlement Period $j$ in the relevant Contracted EFA Block $e$
- $P_{ij}$ is the applicable Market Clearing Price, in GBP/MW/h, for the relevant Contracted EFA Block $e$ and dynamic service Product
- $V_{ij}$ is the Contracted Quantity in megawatts, in respect of Response Unit $i$ and Settlement Period $j$, for the relevant Contracted EFA Block $e$
- $F_{ij}$ is zero (0) if Response Unit I has any period or periods of unavailability for Auction Product a within Settlement Period j at or in excess of (either individually or in aggregate over all such periods) 0.1% of the duration of that Settlement Period, and is one (1) otherwise.

$K_e$ is defined in the remainder of Schedule 2 of the service terms.

Performance Calculations - Overview

The figure below shows an overview of the performance monitoring calculations methodology for all three dynamic services:

\[ S_{ie} = \left( \sum_{j}^{CEB} \text{Round}(P_{ij} \times V_{ij} \times 0.5) \times F_{ij} \right) \times K_{e} \]

**Figure 7:** Overview of the performance monitoring methodology
Performance Calculations (1/3)

Stages

1) Contract: In the first stage, contracts are gathered and processed. This defines the services to be monitored.

If unit DC-UNIT1 has a contract for EFA 1 on the 1st of February 2023 the following information could be processed and DC-UNIT1 will be monitored for DC Low only service with a contracted volume of 10MW for EFA 1 on 01/02/2022.

<table>
<thead>
<tr>
<th>Company</th>
<th>Unit Name</th>
<th>EFA Date</th>

<td>2023-02-01T03:00:00</td>
<td>1</td>
<td>DCL</td>
<td>10</td>
<td>1</td>
<td>Batteries</td>
</tr>
</tbody>
</table>

2) Performance bounds equations: Based on the contracted service, the system selects the corresponding equations for the performance bounds calculation, as defined in the Service Terms.

For the above example, the equations used for a Low service contract are:

\[
UB_{LF}(t) = RLD( R_{LF}(F^{lower}(t)), r_{rmin} ) \times P
\]

\[
LB_{LF}(t) = RLU( R_{LF}(F^{upper}(t)), r_{rmin} ) \times P
\]
Performance Calculations (2/3)

Stages

3) Settlement Period (SP) Error: Errors per SP are then calculated based on the schedule 2 of the service terms. The contracted service also defines if there are errors for Low-only, High-only, or Low and High service. Errors are first calculated using the rolling minimum error formula, the lengths of the rolling minimum windows are provided in Table 4.

\[ E = \max_m \left( \text{rolling minimum } es_m \over x \text{ seconds} \right) \]

Examples of error calculations are given the following ‘Use Case’ sections, for each of the contracted services.

Where \( x \) is the length of the rolling minimum window defined by the contracted service as shown in Table 6.

<table>
<thead>
<tr>
<th>Service</th>
<th>Rolling minimum window length (s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DC</td>
<td>0.2</td>
</tr>
<tr>
<td>DM</td>
<td>0.2</td>
</tr>
<tr>
<td>DR</td>
<td>2</td>
</tr>
</tbody>
</table>

Table 6: Rolling minimum window length by service.

4) Settlement Period (SP) k factor: After errors have been calculated, a k factor is assigned to each SP. The contracted service will also define if there are k factor for Low-only, High-only or Low and High contract.
Performance Calculation (3/3)

Stages

5) Settlement Period (SP) Availability: Availability is calculated based on the availability flag submitted in the performance files. This then defines the availability factor $F_i j_e$ of the payment formula per SP. Availability is first segregated into Low and High service by converting the decimal number into binary, this will determine which service is available, for example:

If a contracted dynamic service is fully available for the full duration of the SP, then a value of 1 is assigned to the availability factor $F_i j_e$. On the other hand, if the contracted service is partly available for the SP, then a value of 0 is assigned to $F_i j_e$.

Recalling the service terms:

"$F_i j_e$ is zero where there is any period or periods of unavailability within Settlement Period $j$ during the relevant Contracted EFA Block $e$, otherwise is $F_i j_e$ 1."

This workflow will be broken down per contracted service below, e.g. for dynamic Low-only, High-only and Low and High service.

6) EFA $K$ factor: The $K$ factor for the contracted EFA block $e$ is calculated using the formula below. This calculates the minimum $k$ factor that occurred within the EFA block.

$$K_e = \min_j k_j$$

$K_e$ factor calculation uses available data to derive the factor. Any unavailability will impact the payment for the affected settlement period.
Dynamic Service Low Performance Monitoring

1) Contract: In the first stage, contracts are gathered and processed. This defines the services to be monitored.

Example, assume that the following contract is given:

2) Low service only performance bounds:

Calculated using the Low service equations:

\[ UB_{LF}(t) = RLU( Ri_F(upper(t)), r_{min} ) \times P \]

\[ LB_{LF}(t) = RLD( Ri_F(lower(t)), r_{min} ) \times P \]

3) Low SP Error: Firstly, measurement errors are calculated, this means that for each sample \( m \), the error is calculated as:

\[ e_m = \begin{cases} 
LB_{LF} - R & \text{if } R < LB_{LF} \\
0 & \text{if } LB_{LF} \leq R \leq UB_{LF} \\
R - UB_{LF} & \text{if } R > UB_{LF}
\end{cases} \]

To calculate the final Low SP Error, the rolling minimum window is used. As defined in Table 6, for DC:

\[ E = \max_m \left( \text{rolling minimum } e_m \right) \text{ over 0.2 seconds} \]

Then the maximum value among the calculated rolling errors within the SP defines the Low SP Error.

4) Low SP k factor: After the Low SP Error (\( E \)) is calculated, for DC the SP k factor for SP \( j \) can be computed as follows.

\[ k_j = \begin{cases} 
1 & \text{if } A \leq E \leq B \\
0 & \text{if } E > B
\end{cases} \]  

Where \( A = 0.03 \) and \( B = 0.07 \).

5) Low SP Availability: Availability is then computed for the SP using the availability flag submitted in the performance files based on the Table 3, e.g. for DC availability.

For 20 Hz sampled data, a full SP contains 36000 rows of data, as per the PerfMon_Excel tool.

For a Low service, the SP Availability can be calculated as:

\[ Availability = \frac{\text{sum}(Low \text{ Availability})}{36000} \]

Then the Availability factor \( Fij \) for SP \( j \) is computed as:

\[ Fij = \begin{cases} 
0 & \text{if } Availability < 0.999 \\
1 & \text{otherwise}
\end{cases} \]

i.e. if a unit has an availability of less than 99.9% then availability factor will be 0 for that settlement period. Otherwise, if the availability is greater than or equal to 99.9% then the availability factor will be 1 for that settlement period.
Dynamic Service High Performance Monitoring

1) Contract: In the first stage, contracts are gathered and processed. This defines the services to be monitored.

Example, assume that the following contract is given:

<table>
<thead>
<tr>
<th>Unit Name</th>
<th>IFA Date</th>
<th>Delivery Start</th>
<th>Delivery End</th>
<th>IFA</th>
<th>Service</th>
<th>Cleared Volume</th>
<th>Leasing Price</th>
<th>Technology Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DC-UNIT1</td>
<td>01/01/2023</td>
<td>01/31/2023</td>
<td>01/31/2023</td>
<td>01</td>
<td>DC</td>
<td>10</td>
<td></td>
<td>1</td>
</tr>
</tbody>
</table>

2) High service only equations:

- High SP Error:
  Firstly, measurement errors are calculated, this means that for each sample \( m \), the error is calculated as:
  \[
  e_m = \begin{cases} 
  \frac{LB_{HF} - R}{R - UB_{HF}} & \text{if } R < LB_{HF} \\
  0 & \text{if } LB_{HF} \leq R \leq UB_{HF} \\
  \frac{R - UB_{HF}}{UB_{HF} - R} & \text{if } R > UB_{HF} 
  \end{cases}
  \]

To calculate the final High SP Error, the rolling minimum window is used. As defined in Table 2, for DC:

\[
E = \max_m \left( \text{rolling minimum } e_m \right) \text{ over 0.2 seconds}
\]

3) High SP Error:

- Calculated using the High service equations:
  \[
  UB_{HF}(t) = RLD(R_{HF}(F_{lower}(t)), R_{min}) \times Q \\
  LB_{HF}(t) = RLU(R_{HF}(F_{upper}(t)), R_{min}) \times Q
  \]

4) High SP k factor:

After the High SP Error (E) is calculated, for DC the SP k factor for SP \( j \) can be computed as follows.

\[
k_j = \begin{cases} 
  1 - \frac{E - A}{B - A} & \text{if } E < A \\
  0 & \text{if } A \leq E \leq B \\
  1 & \text{if } E > B
  \end{cases}
\]

Where \( A = 0.03 \) and \( B = 0.07 \).

5) High SP Availability:

Availability is then computed for the SP using the availability flag submitted in the performance files based on the Table 3, e.g. for DC availability.

For 20Hz sampled data, a full SP contains 36000 rows of data, e.g. using the PerfMon_Excel tool.

For a High service, the SP Availability can be calculated as

\[
\text{Availability} = \frac{\sum(\text{High Availability})}{36000}
\]

Then the Availability factor \( F_{ij} \) for SP \( j \) is computed as:

\[
F_{ij} = \begin{cases} 
  0 & \text{if } \text{Availability} < 0.999 \\
  1 & \text{otherwise}
  \end{cases}
\]

i.e. if a unit has an availability of less than 99.9% then availability factor will be 0 for that settlement period. Otherwise, if the availability is greater than or equal to 99.9% then the availability factor will be 1 for that settlement period.
Dynamic Service Low and High

Performance Monitoring

1) Contract: In the first stage, contracts are gathered and processed. This defines the services to be monitored.

Example, assume that the following contract is given:

<table>
<thead>
<tr>
<th>Company</th>
<th>Unit Name</th>
<th>EIA Date</th>
<th>Delivery Start</th>
<th>Delivery End</th>
<th>EIA</th>
<th>Service</th>
<th>Cleared Volume</th>
<th>Clearing Price</th>
<th>Technology Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPANY1</td>
<td>DC-UNIT1</td>
<td>01/01/2012</td>
<td>01/01/2012 11:00</td>
<td>01/01/2012 23:00</td>
<td>2</td>
<td>DCL</td>
<td>20</td>
<td>1 NA</td>
<td>NA</td>
</tr>
<tr>
<td>COMPANY1</td>
<td>DC-UNIT1</td>
<td>01/01/2012</td>
<td>01/01/2012 11:00</td>
<td>01/01/2012 23:00</td>
<td>1</td>
<td>DC1</td>
<td>50</td>
<td>1 NA</td>
<td>NA</td>
</tr>
</tbody>
</table>

2) Low and High service only equations:

\[
UB(t) = ub(t) \times \begin{cases} 
  p & ub(t) \geq 0 \\
  q & ub(t) < 0 
\end{cases}
\]

\[
LB(t) = lb(t) \times \begin{cases} 
  p & lb(t) \geq 0 \\
  q & lb(t) < 0 
\end{cases}
\]

where

\[
ub(t) = RLD\left( R_{sym}(p_{lower}(t)), r_{min} \right)
\]

\[
lb(t) = RLU\left( R_{sym}(p_{upper}(t)), r_{min} \right)
\]

For a bundled service (Low and High), an extra step is required to separate the calculations of Low and High errors. This is achieved by segregating the performance bounds into LF and HF as follows:

Performance bounds for LF:

\[
UB_{LF}(t) = \begin{cases} 
  UB(t) & UB(t) \geq 0 \\
  0 & otherwise 
\end{cases}
\]

\[
LB_{LF}(t) = \begin{cases} 
  LB(t) & LB(t) \geq 0 \\
  0 & otherwise 
\end{cases}
\]

Performance bounds for HF:

\[
UB_{HF}(t) = \begin{cases} 
  UB(t) & UB(t) < 0 \\
  0 & otherwise 
\end{cases}
\]

\[
LB_{HF}(t) = \begin{cases} 
  LB(t) & LB(t) < 0 \\
  0 & otherwise 
\end{cases}
\]

Figure 10: Example of segregated performance bounds for a DC Low and High service.
Dynamic Service Low and High Performance Monitoring

3) High and Low SP Error. Similarly, the response will be segregated for the calculation of errors, i.e. for response R:

\[ R_L = \begin{cases} R & R > 0 \\ 0 & \text{otherwise} \end{cases} \]
\[ R_H = \begin{cases} R & R < 0 \\ 0 & \text{otherwise} \end{cases} \]

Figure 11: Example of segregated response for DC Low and High service.

Then, measurement errors are calculated for Low and High, this means that for each sample \( m \), the measurement errors are defined as:

\[ e_{mL} = \begin{cases} LB_{LF} - R_L & R_L < LB_{LF} \\ 0 & LB_{LF} \leq R_L \leq UB_{LF} \\ R_L - UB_{LF} & R_L > UB_{LF} \end{cases} \]
\[ e_{mH} = \begin{cases} LB_{HF} - R_H & R_H < LB_{HF} \\ 0 & LB_{HF} \leq R_H \leq UB_{HF} \\ R_H - UB_{HF} & R_H > UB_{HF} \end{cases} \]

To calculate the final Low and High SP Error, rolling minimum windows are used. Then the maximum value among the calculated errors within the SP defines the Low and High SP Error separately.

4) Low and High SP k factor: After the SP Errors (E) are calculated, the SP k factors for SP j can be computed for Low and High as follows.

\[ k_{jL} = \begin{cases} 1 & E_L < A \\ 1 - (E_L - A)/(B - A) & A \leq E_L \leq B \\ 0 & E_L > B \end{cases} \]
\[ k_{jH} = \begin{cases} 1 & E_H < A \\ 1 - (E_H - A)/(B - A) & A \leq E_H \leq B \\ 0 & E_H > B \end{cases} \]

5) Low and High SP Availability: Availability is then computed for the SP using the availability flag submitted in the performance files based on the Table 3, e.g. for DC availability.

For 20Hz sampled data, a full SP contains 36000 rows of data, e.g. using the PerfMon_Ever tool.

For a High service, the SP Availability can be calculated as:

\[ Availability_H = \frac{\text{sum}(High\, Availability)}{36000} \]
\[ F_{iH} = \begin{cases} Availability_H < 0.999 & 0 \\ 1 & \text{otherwise} \end{cases} \]

For a Low service:

\[ Availability_L = \frac{\text{sum}(L\, Availability)}{36000} \]
\[ F_{iL} = \begin{cases} Availability_L < 0.999 & 0 \\ 1 & \text{otherwise} \end{cases} \]
Performance Monitoring

Arming / Disarming

As per Service Terms, the issue of a Disarming Instruction shall not affect payment of the Availability Payment during the relevant Contracted Service Period(s).

In Performance Monitoring, arming/disarming is monitored through the armed flag in the performance data:

Table 8: Armed / Disarmed Status

<table>
<thead>
<tr>
<th>Bit</th>

</table>

When a unit is disarmed, the flag must indicate the relevant status during the disarmed periods. Performance will not be affected by disarmed periods:

When a unit is re-armed, the flag must indicate the relevant status during the armed periods. The performance bounds will be calculated when the armed status is flagged as active:
Performance monitoring

Grace periods

Two types of grace periods can apply when we carry out performance bound calculations. Both cases and relevant examples are described in this guidance.

Grace period 1:
This type of grace period is applied after a response unit begins delivery, after a period of missing data, or after a unit’s availability status switches from ‘unavailable’ to ‘available’. The upper and lower performance bounds will be set to P and -Q respectively.

Grace period 2:
This type of grace period is applied after a contract switch within the dynamic suite as well as switching from FFR to the dynamic suite. The contract used for calculations will be the one giving the lowest lower bound, and the highest upper bound. The performance will be assumed to be 100% during such grace period provided that the scaled error is below 25%.

The lengths of the two grace periods are shown below.

Grace Period 1 – Beginning of delivery

Grace period 1 comprises the following cases:

• Beginning of Delivery
• Period of Missing Data
• Switching from Unavailable to Available.

Beginning of Delivery

Beginning of delivery is defined as the start of a dynamic service delivery from any other service not within the dynamic service suite or FFR. For example, if a unit is contracted for a 50MW DC L-only service in EFA 2, EFA 4 and EFA 5, the grace period 1 (for DC, 0.55 seconds grace period) will be applied to the beginning of EFA 2 and EFA 4 only as there are no dynamic service contracts before the beginning of the specified EFAs.

Figure 14: Example of performance bounds without grace period 1 at the beginning of delivery.

Figure 15: Example of performance bounds without grace period 1 at the beginning of delivery.
Grace Period 1 – Missing data period

**Missing Data Period**

Missing data is defined as gaps in the sampled data, e.g. for 20Hz sampled data, the time intervals will have increments of 50ms for each sample. Then, if the interval is greater than 50ms, the grace period will be applied.

**Figure 16: Missing data example**

Grace Period 1 – Availability switch

**Availability Switch**

When a unit switches from unavailable to available the Grace period 1 will be implemented. This applies within every service of the dynamic suite.

The following combinations have been provided as an example for DC. This approach is also applicable to DM and DR in the same way using the respective availability flags for each service.

Grace Period 1 – Availability switch

Availability Switch

The following combinations have been provided as an example for DC. This approach is also applicable to DM and DR in the same way using the respective availability flags for each service.

Figure 17: Example of availability changes for DC L

Figure 18: Example of availability changes for DC H
Grace Period 2

Grace period 2 is applicable after a contract switch within the dynamic suite (also considering switching from FFR to the dynamic suite) using whichever of the contracts gives the lower bound, and the higher upper bound.

A non–exhaustive list of scenarios where the grace period 2 will be applicable is given below.

**DR switches (10 seconds grace period)**
- DRL to DRH/DRLH
- DRH to DRL/DRLH
- DRL to DRL (if there is a change in P)
- DRH to DRH (if there is a change in Q)
- FFR to DR
- DC/DM to DR

**DC switches (2 seconds grace period)**
- DCL to DCH/DCLH
- DCH to DCL/DCLH
- DCL to DCL (if there is a change in P)
- DCH to DCH (if there is a change in Q)
- FFR to DC
- DM/DR to DC

**DM switches (2 seconds grace period)**
- DML to DMH/DMLH
- DMH to DML/DMLH
- DML to DML (if there is a change in P)
- DMH to DMH (if there is a change in Q)
- FFR to DM
- DC/DR to DM
This type of grace period is applied after a contract switch within the dynamic suite as well as switching from FFR to the dynamic suite.

This change will provide the corresponding grace period where the Upper performance bound and the Lower performance bound will be calculated using whichever of the contracts gives the lowest lower bound (LB), and the highest upper bound (UB). The performance will be assumed to be 100% during such grace period provided that the scaled error is below 25%.

This can be defined as follows, for two consecutive DC L-only contracts EFA 1 with \( P_1 \) switch to EFA 2 with \( P_2 \):

\[
UB_1(t) = RLD \left( R_{LF} \left( F_{lower}(t) \right), rr_{min} \right) \times P_1
\]
\[
LB_1(t) = RLU \left( R_{LF} \left( F_{upper}(t) \right), rr_{min} \right) \times P_1
\]

and

\[
UB_2(t) = RLD \left( R_{LF} \left( F_{lower}(t) \right), rr_{min} \right) \times P_2
\]
\[
LB_2(t) = RLU \left( R_{LF} \left( F_{upper}(t) \right), rr_{min} \right) \times P_2
\]

Then LB and UB are calculated for 2 second after the change, i.e. at the beginning of EFA 2, as:

\[
UB_{LF}(t) = \max (UB_1(t), UB_2(t))
\]
\[
LB_{LF}(t) = \min (LB_1(t), LB_2(t))
\]

The scaled error will then be calculated as:

\[
e_m = \begin{cases} 
LB_{LF} - R & R < LB_{LF} \\
0 & LB_{LF} \leq R \leq UB_{LF} \\
R - UB_{LF} & R > UB_{LF}
\end{cases}
\]

\[
es_m = \begin{cases} 
\frac{e_m}{P_2} - 0.25 & \frac{e_m}{P_2} > 0.25 \\
0 & \frac{e_m}{P_2} \leq 0.25
\end{cases}
\]
Energy Requirement and Duration

Energy limited as an asset type is defined in the Glossary as:

a classification given in the Registration and Pre-Qualification Procedure to any Auction Unit comprised of one or more Eligible Assets:

(a) which creates its store of energy by using power ultimately drawn from the National Electricity Transmission System; and
(b) whose State of Energy at the start of a relevant Service Period is insufficient to provide full delivery of the Contracted Quantity for the duration of that Service Period;

These assets are subject to a number of additional rules detailed in section 6 of the Service Terms. One area of additional rules relates to; delivery duration, response energy and energy recovery.

The rules are required to give ESO assurance that energy limited assets can reliably provide the full contracted quantity of dynamic services. The duration and volume requirements have been sized based on analysis of frequency events and a risk-based assessment.

The terms below are fully defined in the Glossary. Below a plain English explanation is offered.

1. Contracted Quantity
   a. The amount of Response (MW) which a Service Provider has agreed to provide.

2. Delivery Duration
   a. fifteen (15) minutes (DC)
   b. sixty (60) minutes (DR)
   c. thirty (30) minutes (DM)

3. Response Energy Volume
   a. the amount of stored energy (or capability to store energy) that a Response Unit should be capable of delivering before becoming unavailable due to exhaustion. Calculated as the Contracted Quantity multiplied by the Delivery Duration.

4. Energy Recovery
   a. the minimum volume of stored energy (or capability to store energy) capable of being recovered by way of State of Energy management in a single Settlement Period. Calculated as twenty percent (20%) of Response Energy Volume.
Physical Notifications

Physical Notifications (PNs) are used as the accepted Operational Baseline to state what a unit's expected profile will be for an upcoming Settlement Period.

Response Units that are also registered in the BM are required to submit an operational baseline in the form of a physical notification to the BM System. From Release 1 go-live, Response Units that are not registered in the BM will be required to submit an operational baseline in the same way but in to the ASDP System.

**Settlement Period:** A 30 minute period starting either on the hour or half hour which is the resolution at which payments are settled.

**Gate Closure:** The time 60 minutes prior to the start of the Settlement Period. After this time the PN can no longer be submitted or changed for the applicable Settlement Period. This is to allow ESO time to balance the market without further changes.

*Example:*
*If the settlement period is 14:00-14:30, then Gate Closure is 13:00*

**PN formatting**

A PN takes the form of a CSV file which is entered into the BM or ASDP system using the following format:

```
BMU_ID, Start datetime, End Datetime, Start MW, End MW
```

The **BMU_ID** is assigned to a unit via the registration process at the start of an assets life.

The **datetime** must be in GMT all year and must have at least 1 minute resolution.

For BM, **MW** values must be declared as integers.

Using this data the system can build a graphical profile (baseline) of what each unit will be doing. A PN does not need to be a static value, it can change over the duration of the Settlement Period.
Ramp Rates

Some providers are capable of powering up or down extremely quickly, which makes them a valuable source of flexibility but this can also pose as a challenge as it can also lead to frequency volatility.

For some services, including all dynamic response services when actions are taken in the opposite direction to the response contract, we require participants to turn up or down more slowly to help keep the grid stable, the rate at which they power up or down is called the ramp rate.

There is a ramp rate limit applicable to all baselines submitted during contracted periods. A baseline cannot have a ramp-rate greater than 5% of the contracted quantity per minute. When stacking services with the introduction of EAC the ramp rate will be 5% of the sum of all stacked service.

Examples

The Ramp Rate will differ depending on the size of the frequency response contract:

**Table 13:** Ramp Rate Examples

<table>

</tr>
</tbody>
</table>
The State of Energy Management (SoE) rules and requirements are set to ensure that energy-limited units remain able to provide the contracted services on a continuous basis. The rules are applicable for BM and NBM units.

The current SoE monitoring practices allow us to identify the situations where a unit is allowed to declare unavailability due to excessive delivery of response services. This situation could arise if the unit follows the SoE rules in full and runs out of SoE. SoE monitoring also allows us to monitor that units follow the management rules during such situations, where an unavailability is treated as available in terms of payment.

The applied methodology relies on monitoring the lower boundary of the required SoE, which is calculated based on the requirement stated in the Service Terms and reflects the minimum SoE level that the unit should hold. The SoE level of the unit should always be greater than this lower boundary. Instances where this lower boundary hits zero (due to extreme system conditions such as extended periods of high or low system frequency deviation - beyond 0.2 Hz above or below 50 Hz) are read as situations where the unit could be potentially depleted.

**Requirements –**
1. Being able to provide the required amount of energy defined as Response Energy Volume in Service Terms 6.11.i2
2. Being able to recover the amount of energy defined as Energy Recovery in Service Terms 6.11.ii
3. Compliance with the baseline ramp rate requirement in Service Terms 6.8.

**Recommendations -**
1. Prepare the appropriate headroom and/or footroom so the unit can provide the full Contracted Quantity at all moments during the service delivery time. This means service providers can decide the level of headroom and/or footroom to hold, this level could potentially be zero except in the situation where the unit provides maximum symmetrical capacity for both LF and HF - it must retain some headroom for energy recovery.
2. The unit can choose to recover the energy faster, i.e. recover more energy than Energy Recovery. However, this must ensure any baseline complies with the maximum ramp-rate rule.

**General SoE management guidelines**
SoE management for DC/DM/DR should rely on energy-limited units:
1. Beginning the EFA Block with a level of stored energy adequate for their contracted response quantity.
2. Reviewing the level of stored energy at the start of each settlement period during that EFA Block, looking at the net energy delivery in the previous settlement period.
3. Aim to return the stored energy to an appropriate level by following the submitted operational baselines, charging or discharging according to them.
SoE for BM and NBMs

Example:

- **Contracted quantity**: 50MW of DC low (i.e. low frequency response only)
- **Minimum energy requirement**: 12.5MWh - calculated as 15 minutes at full power: \((15/60) \times 50 = 12.5\text{MWh}\)
- **Minimum energy recovery requirement**: 2.5MWh per SP - calculated as 3 minutes at full power: \((3/60) \times 50 = 2.5\text{MWh}\)

Based on the above parameters, the Registered Service Provider should therefore manage the SoE of its energy limited unit as follows:

1. Begin the EFA Block with the capability to deliver 12.5MWh of energy in the relevant direction – in this case, generation when frequency is low. Delivery might occur in a single event lasting 15 minutes at full power or any number of shorter consecutive events (see Note 1 at the end of this section).

2. At the start of each (and every) settlement period during that EFA Block, the Registered Service Provider should calculate the net energy delivery over the preceding settlement period. For example, if in SP24 the unit delivered 10MWh of energy as it responded to frequency, at the end of SP 24 / start of SP25 the stored energy is now 2.5MWh.

3. The Registered Service Provider should submit a baseline to replenish at least 2.5MWh so that stored energy can begin to return to minimum requirement. The baseline should not exceed a level at which the unit is unable to continue to provide DC whilst following the baseline.

   a. The Registered Service Provider should create and submit this baseline before the end of SP25 so that it can take effect from SP28. It cannot take effect any earlier because there is a 1 hour gate before baselines can apply – this is the convention applied to physical notifications in the BM and needs to be mirrored by non-BM providers to ensure fairness across all market players.

   b. The baseline should replenish at least 2.5MWh because this is the minimum energy recovery requirement calculated as 20% of the minimum energy requirement (equal to 3 minutes at full power: \((3/60) \times 50 = 2.5\text{MWh}\)).

Illustration in next slide..
SoE for BM and NBMs

Illustration

If there is no further response delivered in SPs 25-31 (i.e. frequency stays in the dead band 50Hz +/- 0.015) then the stored energy will be 5MWh at the end of SP28, 7.5MWh at the end of SP29, 10MWh at the end of SP30 and completely restored to 12.5MWh at the end of SP31. At the end of every Settlement Period the Registered Service Provider assesses the level of stored energy and submits an appropriate baseline to recover that energy at a rate of at least 20% per Settlement Period.

The Registered Service Provider can choose to recover the energy faster but must ensure any baseline complies with the maximum ramp-rate rule. In our example the maximum ramp rate is calculated as 5% of the contracted quantity, so 2.5MW/min.

Figure 19: State of Energy Management
The Registered Service Provider must also ensure that the contracted service can be delivered at all moments during the service delivery day, including when ramping to or delivering against baselines for energy. This means a unit with name-plate capacity of 50MW cannot be contracted to deliver 50MW of symmetrical DC – it must retain some headroom for energy recovery.

NGESO is not specifying how much headroom a unit must hold; that will depend on unit characteristics unknown to NGESO, e.g. cycle efficiency (See Note 3). The Registered Service Provider can assess what quantity of the contracted service a unit can provide whilst considering:

1. The requirement to recover at least 20% of the minimum energy requirement in a single Settlement Period.
2. The maximum ramp rate for all baselines submitted during the EFA Block.
3. The unit efficiency and other technical and commercial considerations.

Additional notes:

Note 1: For energy limited units, please take note that the energy requirement is defined in terms of MWh, not minutes. It can be calculated in terms of minutes at full power but should not be interpreted as ‘maximum delivery time is 15 minutes’. Units are required to deliver at least the minimum energy requirement, for example for DC this could be full power for 15 minutes but could also be 50% power for 30 minutes or 10% power for 150 minutes. There is no maximum delivery time unless/until the minimum energy requirement is fully delivered in net terms and/or the contracted MWh volume is less than 1MW (i.e. 1MW minimum contracted DC volume).

Note 2: For all Registered Service Providers, we will calculate your response delivery as a deviation from your submitted operational baseline. Therefore, the ability to accurately follow a baseline is paramount. In the dead band (+/- 0.015Hz) the unit should be operating at its baseline – this may be 0MW or any other value, particularly if the unit is following a baseline to charge/discharge for SoE management purposes. The difference between a unit’s baseline at its maximum capacity should be greater than or equal to the total contracted quantity, otherwise it would not be able to deliver on its obligation if frequency moved to +/-0.5Hz.

Note 3: It is not possible or desirable for NGESO to prescribe the maximum quantity that an energy limited asset can provide. We do not know the cycle efficiency (or how this might change over time) so we cannot prescribe how much headroom/foot room must be maintained to allow for adequate SoE management. We can only be sure that a xMW capacity unit can offer < xMW of symmetrical service.
Notes on Stacking of services:

**Note 4:** When considering stacked products, the minimum energy requirement should be calculated as the sum of the minimum energy requirements of each product.

Example:

**Contracted quantity:** 10MW of DC low and 10MW of DM low

DC minimum energy requirement: 2.5MWh - calculated as 15 minutes at full power: \((15/60) \times 10 = 2.5\text{MWh}\)

DM minimum energy requirement: 5MWh - calculated as 30 minutes at full power: \((30/60) \times 10 = 5\text{MWh}\)

**Total minimum energy requirement:** 2.5MWh + 5MWh = 7.5MWh

DC minimum energy recovery requirement: 0.5MWh per SP - calculated as 3 minutes at full power: \((3/60) \times 10 = 0.5\text{MWh}\)

DM minimum energy recovery requirement: 1MWh per SP - calculated as 6 minutes at full power: \((6/60) \times 10 = 1\text{MWh}\)

**Total minimum energy recovery requirement:** 0.5MWh + 1MWh = 1.5MWh

**Note 5:** For energy limited providers, the rules impose a maximum ramp-rate on any submitted baseline. The current limit is 5% of contracted quantity per minute. Furthermore, as referred to in paragraph 6.9i of the Service Terms, the maximum ramp rate will depend on whether the Response Unit is providing LF or HF or both, and whether its Baseline is showing either an increase or reduction in level of Active Power Output or an increase or reduction in level of Demand. When considering stacked products, the total **Contracted Quantity** for LF or HF should be considered when calculating the maximum ramp-rate.

Example:

**Contracted quantity:** 10MW of DC low and 10MW of DM low

Total Low contracted quantity: 20MW

Maximum ramp-rate: \(20 \times 0.05 = 1\text{ MW/min}\)
Instruction Codes

Instruction and Reason codes

Reason codes are issued for BMUs. ASDP sends instructions for Non-BMUs.

These are used to send instructions to providers in real time. The DNS ‘disarming’ code in particular instructs units to cease provision of the contracted response service(s) until a ‘rearming’ code is sent.

DNS is the only code used for disarming instructions currently, and can be used across all services. Rearming, on the other hand, is instructed using service-specific codes such as DC for the Dynamic Containment Respons or DCL for Dynamic Containment Low Response services.

DNS: Cease Contracted Response Service(s). Note that this does not remove the grid code obligations.

Table 14: List of Live Reason Codes

Table 15: List of Reason Codes form release 1B (2024)
Reason Codes Examples

Example 1: Simple disarm / re-arm
Unit A is armed and currently contracted to provide DCH
Unit A is sent instruction with the reason code XCH (disarm DCH)
⇒ Unit A accepts the instruction and is disarmed, ceasing to provide DCH
While Unit A is contracted, Unit A is sent an instruction with the reason code DCH (re-arm DCH)
⇒ Unit A accepts the instruction, is re-armed and resumes its DCH service.

Example 2: Stacking disarm/re-arm
Unit C is armed and currently contracted to provide DCH and DRL
Unit C is sent an instruction with the reason code XRL (disarm DRL)
⇒ Unit C accepts the instruction, is disarmed for DRL and ceases to provide DRL. However, it remains armed for DCH and continues to provide DCH
While Unit C is contracted, Unit C is sent an instruction with the reason code DRL (re-arm DRL)
⇒ Unit C accepts the instruction, is re-armed for DRL and resumes its DRL service. There is no change in the DCH service.
Operational Data
Availability Service Inbound

This section provides guidelines for submitting availability data. Frequency Response Ancillary Services (Dynamic Moderation (High/Low), Dynamic Containment (High/Low) and Dynamic Regulation (High/Low)) can submit the availabilities using the OfferBid array for a particular Availability Window or a group of Windows as required. In the event of any conflict or inconsistency between this document and the Service Terms, the latter shall prevail.

Further details and guidance on availability can be found here.

Guidelines:

1. Service Providers should invoke the Availability webservice to submit any declarations or redeclarations for all Ancillary Services.
2. Service Providers can send availabilities for multiple windows using a single xml, multiple OfferBid arrays in a single AvailabilityWindow where applicable.
3. Service Providers would invoke the Webservice as per the WSDL url: https://test.pas.nationalgrid.com/services/V3_Sandbox_ConsumeAvailabilityService?wsdl and sample payloads in Appendix 1A.
4. National Grid ESO will Accept/Reject the availability (through Availability Confirmation web service 3.2) for a specific availability window as specified in business logic document.
5. AUI should have 15-18 characters in total with the following algorithm to make it unique to 1 in million times. This field is used for traceability purposes. See example payloads in Appendix for reference.
   a) First 3 characters will have ‘AUI’
   b) Next 2 characters will be random lowercase alphabets from a-z
   c) Next characters will be a random number from 1 to 9999
   d) Next 3 characters will be random uppercase alphabets between A-Z
   e) The last 6 characters will be MMHHdd (where MM is month e.g. 08; HH is hours e.g. 16; dd is date e.g. 28) So, an example AUI will be ‘AUJxq34YMU081816’
Registered Service Providers will be required to submit both Operational and Performance Data, as outlined in the Service Terms.

All performance data is to be submitted via the Data Concentrator. Operational data should be submitted via BM systems (e.g. EDT/EDL) and for non-BM by ASDP.

Details on how to connect to these platforms and further technical detail can be found on the New Dynamic Service webpage. The published files contain high level overview and more in depth technical details are shared on a one to one basis securely. Details to access these are outlined in the documents. These are alongside other existing BM systems such as EDL/EDT and the Wider Access API for Physical Notifications and other Dynamic Data submissions required under the Grid Code for BM units.

NGESO will seek to publish data in line with our other balancing services in the Monthly Balancing Services Summary (MBSS). NGESO will also seek to provide a service specific report covering performance of the DC/DM/DR services and daily auction results. NGESO website shall be used for publishing documentation on the Dynamic services.
Settlements
Settlements

For each EFA Block the subject of a DC/DM/DR Response Contract, the applicable DC/DM/DR product will be settled against the market clearing price (£/MW/h) for that EFA Block and DC/DM/DR product established pursuant to the relevant Auction Rules. For further information regarding how Availability Payments are calculated, and payment terms, please refer to the Service Terms.

NGESO shall apply DC/DM/DR energy volumes within Applicable Balancing Services Volume Data (ABSVD) for BM units only. It is the responsibility of each Registered Service Provider to ensure that the relevant BM Unit Lead Party has made the appropriate election.

In addition, where it has not already done so, each Registered Service Provider must ensure that it has completed the necessary vendor setup forms that are outlined on our Settlement webpage to be set up as a vendor on NGESO’s systems. These should be submitted as soon as possible so that we make payments in a timely manner in accordance with the Service Terms.
1. **Service Data** – This is operational data relating to the provision of a service and is used to calculate monies owed, e.g. metering data, contracted mW, etc.

2. **Contact and billing data** – This is customer and company contact information, such as email recipients, billing addresses, etc. If you are setting up as a new service provider, please refer to the New Service Provider Guidance document.

3. **Settlements system** – Service, contact and billing data is collated in the Settlements system where calculations for monies owed takes place.

4. **Invoices and backing data produced** – This information is produced at D+8 (preliminary) and D+18 (final). Please note that the preliminary billing process does not include the creation of invoices or the instruction of payments to the Finance team.

5. **Provider emailed** - Invoice and backing data is email to the provider.

6. **Finance instructed to release payment** - Finance are instructed to release payment to the provider.

---

Updates from EAC
Go Live
Performance Monitoring

This section provides information on the application of the performance monitoring methodology for the New Dynamic Services following the go live of Enduring Auction Capability (EAC). In the event of any conflict or inconsistency between this document and the Service Terms, the latter shall prevail.

Availability Payments

With respect to each Response Contract, a settlement value shall be calculated for each Settlement Period in accordance with the following formula:

\[ S_{aij} = \text{Round} \left( P_{aij} - \left( 1 - K_{aij} \right) \times PF_{aij} \right) \times V_{aij} \times 0.5 \times F_{aij}, 2 \]

Where:

- \( S_{aij} \) is the settlement value calculated in respect of Response Unit \( i \) for the relevant Auction Product \( a \) and Settlement Period \( j \);
- \( P_{aij} \) is the applicable Market Clearing Price in £/MW/h for the relevant Auction Product \( a \) and Settlement Period \( j \);
- \( V_{aij} \) is the Contracted Quantity in MW in respect of Response Unit \( i \) for the relevant Auction Product \( a \) and Settlement Period \( j \);
- \( F_{aij} \) is zero (0) if Response Unit \( i \) has any period or periods of unavailability for Auction Product \( a \) within Settlement Period \( j \), and is one (1) otherwise;
- \( K_{aij} \) is the performance factor in respect of Response Unit \( i \) for the relevant Auction Product \( a \) and Settlement Period \( j \), and is defined in this Schedule 3 below; and
- \( PF_{aij} \) is the settlement adjustment price in £/MW/h applicable to Auction Product \( a \) and Settlement Period \( j \), and is which is calculated as follows:
  - The settlement adjustment price is equal to the Market Clearing Price if the Market Clearing Price is greater than or equal to \( [x2] \);
  - The settlement adjustment price is equal to -1 (negative one) times the Market Clearing Price if the Market Clearing Price is less than or equal to \( [x1] \);
  - The settlement adjustment price is equal to \( [X] \) if the Market Clearing Price is between \( [x1] \) and \( [x2] \).

As per the performance monitoring section of this document the \( F_{ij} \) value currently includes a 0.1% threshold for availability within a settlement period, this clarification has been included as part of the proposed documents for release 2.
Performance Monitoring

Stacking

- When stacking response services, a single K-factor for the asset will be calculated.
- The amount the participant will get paid for each service with the combined K-factor will be the same as if they were delivering a single, unstacked service with that same K-factor.
- This minimises the risk that a participant may game the penalty when stacking by underperforming on the least valuable service delivering perfectly on the more profitable service.

Example

In this example, we have a single participant providing stacked services: Service 1 and Service 2. The total capacity of the asset is 100 MW, so if the participant clears 100% of its capacity at £1/MW/h it would receive payment of £50 for a settlement period of 30 min.

Table 16: Volume cleared for service 1&2

<table>
<thead>
<tr>
<th></th>
<th>Volume cleared (MW)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service 1</td>
<td>60</td>
</tr>
<tr>
<td>Service 2</td>
<td>40</td>
</tr>
</tbody>
</table>

The following figures show the total payment vs the K factor (which measures performance against the service envelope) for both services.

Same Clearing Price Example

In this example, the market clearing price (MCP) is the same for both services i.e., £1/MW/h. As the market clearing prices (MCP1 and MCP2) are both greater than zero, then total payment from ESO to the participant decreases as performance decreases. Figure 18 Shows how the total payment is composed by a proportion from Service 1 and another portion for Service 2. Each portion is proportional to the volume cleared for each service and the price at which it was cleared.

Figure 22: Example of penalties for stacked services with MCP1>0 and MCP2>0.
If the clearing prices are different, each service is penalised in proportion to its cleared volume and price. For instance, if MCP1 > 0 but MCP2 < 0 then penalties from poor performance from Service 1 should reduce the amount that the ESO pays the participant whereas penalties from poor performance from Service 2 should increase the amount that the participant pays ESO. Figure 19 Shows this case for different K factors. For example, if the market clears at MCP1 = £1/MW/h and MCP2 = -£1/MW/h, and the asset delivers with a K factor of 0.5, payment from ESO to the participant for a single settlement period of each service can be calculated as applying:

\[ \text{Payment}_{S1} = 60\text{MW} \times 0.5\text{h} \times (-2\text{£}/\text{MW/h} - (1-0.5) \times 1\text{£}/\text{MW/h}) = -75\text{£} \]

\[ \text{Payment}_{S2} = 40\text{MW} \times 0.5\text{h} \times (1.5\text{£}/\text{MW/h} - (1-0.5) \times 1.5\text{£}/\text{MW/h}) = 15\text{£} \]

\[ \text{Total Payment} = \text{Payment}_{S1} + \text{Payment}_{S2} = -75\text{£} + 15\text{£} = -60\text{£} \]

**Figure 23:** Example of penalties for stacked services with MCP1 > 0 and MCP2 < 0.

Consequently, total payment to the participant would be -60£ (participant pays ESO £60).
